Day high/low guard: don't buy at the top

PalTra · Settings → 1. When to enter · "Don't buy at the day's high or short at the day's low: wait for a pullback". Examples on a ₹1,000 stock with the default numbers (0.15%, 0.15%, 3 candles). The candles are made up; the levels use the bot's own rule.

The idea in one line

In a strong move the buy signal often comes on the candle that closes **right at the day's high**. Buying there means buying the most stretched price of the day, and the first small dip turns the trade into a loss. With this tick box on, the bot **waits for a small dip** before buying (or a small bounce before shorting).

The bot waits for the price to come down to the buy level (or to the SMA 9 if that is nearer, i.e. higher). It buys at the first touch within **3 closed candles**. No touch in 3 candles → no trade (the move is let go).

A short works the same way upside down: near the day's low it waits for a bounce up before selling.

The three boxes

Box	Default	What it means	On a ₹1,000 stock
Near the high/low (%)	0.15	How close to the day's high (for a buy) or day's low (for a short) the signal candle must close for the guard to step in. Further away = the bot orders at once as usual.	within ₹1.50 of the day's high
Wait for a pullback of (%)	0.15	How far back from the signal candle's close the bot wants to buy (below it) or sell (above it). If the SMA 9 line is nearer than that, the bot uses the SMA 9 instead.	buy ₹1.50 below the close
Wait at most (candles)	3	How many closed candles it waits for that price. No pullback in time = no trade. It also gives up if the SMAs cross the other way, at the entry cut-off or the trade limit.	3 candles (45 min on 15-min candles)

Everything else still applies to the order when it fills: your entry checks, the stop-loss, the cut-off, the trade limits and, on LIVE, one LIVE bot per stock. Nothing waits on Groww's order book: the bot sends the normal order the moment the price touches the level.

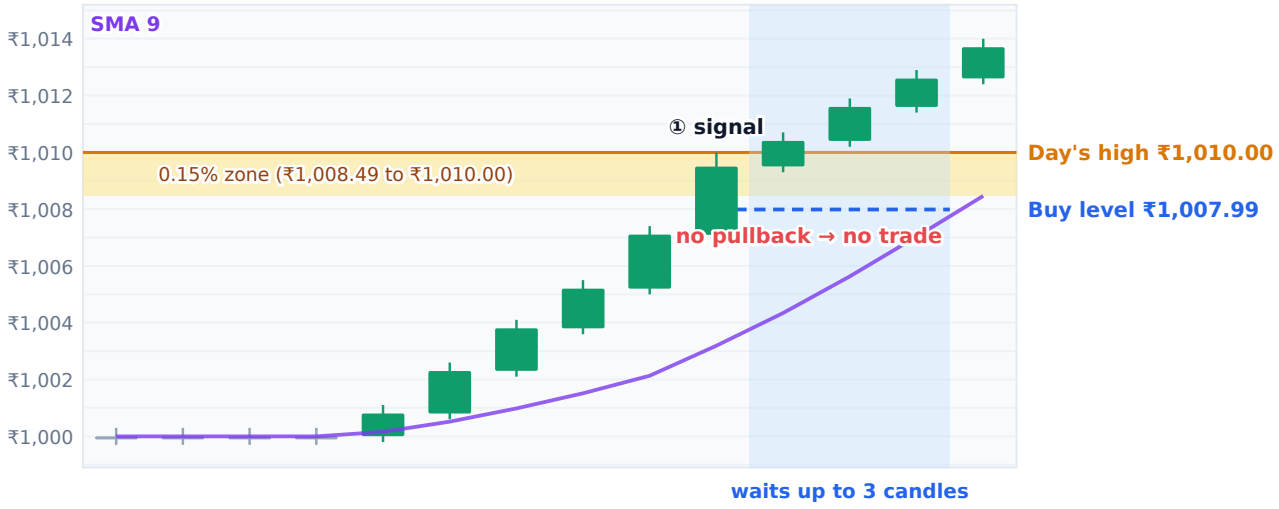

Example A · signal at the high, the dip comes → a cheaper buy

① The signal candle closes at ₹1,009.50, only ₹0.50 under the day's high ₹1,010.00, inside the yellow 0.15% zone. The bot does **not** buy yet.

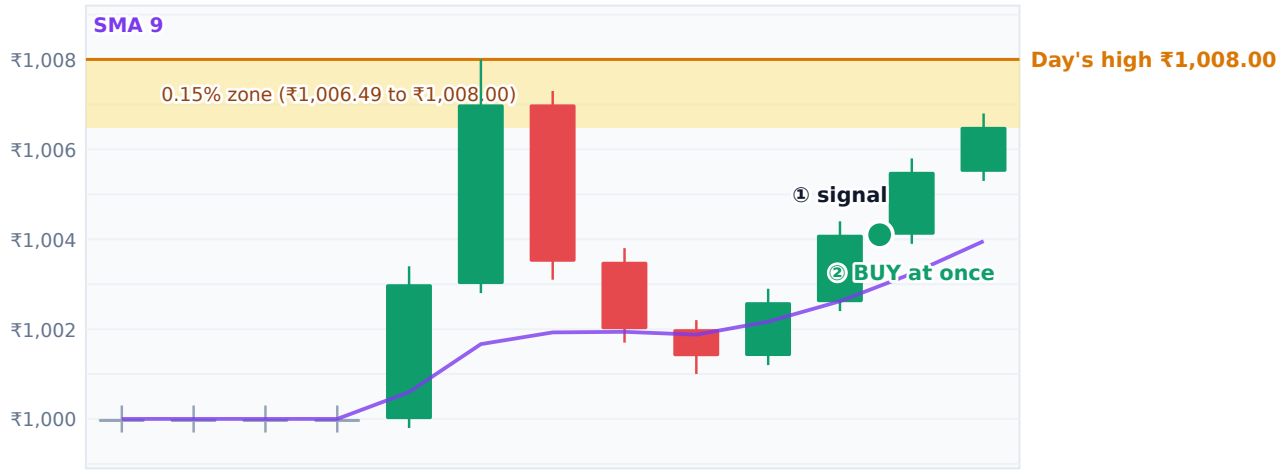

② Two candles later the price dips to the buy level **₹1,007.99** and the bot buys there, ₹1.51 cheaper per share than buying at the signal (₹151 better on 100 shares), with more room before the stop.

Example B · signal at the high, no dip → no trade

The price keeps climbing and never comes back to ₹1,007.99 within 3 candles, so the bot lets the move go: **no trade**. This is the price of the guard: it skips some runners to avoid buying many tops.

Example C · signal well below the day's high → buys at once

The day's high (₹1,008.00) came from an early spike. The signal closes at ₹1,004.10, 0.39% below it, outside the 0.15% zone, so the guard does nothing and the bot orders at once as usual.

Example D · a short near the day's low waits for a bounce

The sell signal closes at ₹990.50, within 0.15% of the day's low ₹990.00. The bot waits for a bounce up to **₹991.99** and sells there on the 2nd candle.

Tips

If you want…	Change
The guard to step in more often	Raise **Near the high/low** (e.g. 0.30%).
A deeper, cheaper entry	Raise **Wait for a pullback of** (e.g. 0.25%) — fewer trades fill.
To miss fewer runners	Lower **Wait for a pullback of** (e.g. 0.08%) or raise **Wait at most** (e.g. 5).

Notes: the tall-candle pullback and the candle-extreme limit entry, when on, take over from this guard (they already wait for a better price). It does not apply to candle-pattern or candle-colour entries. Trades that fill this way show the entry reason with ":PULLBACK". Try changes on Replay first.
